PDF A case-control study is a type of observational study commonly used to look at factors associated with diseases or outcomes. Inferential reasoning is from cause to effect. The prevalence (or The generally accepted term case-control study derives from the usual dichotomous categorization of outcome as present (cases) or absent (controls)Research Design Case-control studies are one of the major observational study designs for performing clinical research. After the investigator determines the exposure, a table can be formed from the study data. In case-control studies, on the other hand, we start with the outcome and ask or find out about prior exposure. A case-control study involves the identification of individuals with ('cases') and without ('controls') a particular disease or condition. In cohort studies (and clinical trials), subjects are followed in a forward direction from exposure to outcome.
