The raise climber is developed with three kinds of drive units: air driven, electrically driven, and diesel/hydraulically driven. Alimak Company (Sweden) introduced this technique in, and even today, it is often used in driving blind raises which have long lengths. The method traditional raising, mechanical raise climber excavation (commonly referred to as Alimak raising), drop/longhole raises, and pilot and slash developments where a small-diameter raise is first driven (by raisebore or raise climber methods) and then slashed out to full diameter from the top down. Other, less Alimak Raise Excavation. Raise development using a Mechanized Raise Climber (Alimak) is a preferred method for developing escapeways, ventilation raises, ore/waste passes, and slot raises in underground mines. Jora raising method is suitable only for the condition when two levels are available for connectivity by a raise. Drilling and blasting are the most common methods for tunnelling and underground excavation.
