describes how the velocity  $v(t)$  of a falling object changes when the object is assumed to be under the influence of We introduce a version of Existence and Uniqueness theorem for first order ODEs, which gives sufficient conditions for a solution of an initial value problem to exist locally (i.e., Example Here we have a system of two equations.  $M a, b$ . In this section we state such a condition and illustrate it with examples LECTUREThe Fundamental Existence and Uniqueness Theorem For  $n$ -th order Differential Equations (Text: Chap)Introduction In this lecture we will state and sketch the proof of the fundamental existence and uniqueness theorem for the  $n$ -th order DE  $y^{(n)} = f(x; y; y'; \dots; y^{(n-1)})$   $y(0) = g$   $k \geq 0$ . We start by relating the initial value problem ( $y(0) = f(x$  One reason is it can be generalized to establish existence and uniqueness results for higher-order ordinary differential equations and for systems of differential equations. min. Picard's Existence and Uniqueness Theorem So for example if we chose  $h$  (which is less than  $1/48$ ), we would deduce that there is a unique solution in the interval  $[-h, h]$ . Another is that it is a good introduction to the broad class of existence and uniqueness theorems that are based on fixed points. For the proof of existence and uniqueness one first shows the equivalence of the problem (I) to a seemingly more Whether we are looking for exact solutions or numerical approximations, it is useful to know conditions that imply the existence and uniqueness of solutions of initial value problems. Then there is a unique function  $x \mapsto y(x)$ , defined for  $x$  in  $I_h(x_0)$ , 1 Existence and UniquenessSome BasicsUniqueness TheoremContinuityExistence TheoremLocal Existence Theorem and The Peano ExampleIn physics, the differential equation. III. The initial value problem (I) is equivalent to an integral equation. The second existence proof uses a fixed-point argument. Then we'll finish up by presenting two different proofs of uniqueness.  $u_1'(t) = -u_2(t)$   $u_2'(t) = u_1(t)$  with initial conditions  $u_1(0) = a$  and  $u_2(0) = b$  The (unique) solution of this happens to be  $u_1(t) = \cos t$  existence proof is constructive: we'll use a method of successive approximations – the Picard iterates – and we'll prove they converge to a solution. Let  $I_h(x_0) = [x_0 - h, x_0 + h]$ , where  $h$ . TheoremSuppose that  $F$  satisfies the assumptions above.
