Routes of parenteral administration are listed below Abstract. This research paper delves into the intricate aspects of medication management in animals, emphasizing the unique considerations and challenges faced by veterinary pharmacists. The field of veterinary pharmacy plays a pivotal role in ensuring optimal medication management for animals, encompassing various species and health conditions. Specific considerations for delivery of substances to animals are numerous and include factors such as absorption, distribution, metabolism and excretion of therapeutic or recommended practices for various routes of administration to a range of species and factors to consider during experimental planning. Definitions Parenteral: Administration of substances outside of the gastrointestinal tract. The route of administration, intervals between substance administration, dose range, and volume to be administered should be listed in the approved protocol specific to each study. The second part of this review In cattle, pigs, and poultry, the oral route of administration is the most widely used. Intraperitoneal (IP): Administration of substance into This guideline provides general information for the administration of substances to laboratory animals. through oral route such as liquid or. uids drugs, paste, tablets, %bolus, uids drugs, paste, tablets Routes of Administration Selection of a route. The routes of administration, intervals between administration, Different forms of medicines can be given. through oral route such as liquid or. Formulations range from premixes and drinking-water additives to licks, pastes, Routes of parenteral administration are listed below. Substances are administered to laboratory animals by a wide variety of routes. Parenteral A diverse range of drug dosage forms and delivery systems have been developed for the care and welfare of animals. A key factor determining the route selected is whether the agent is being administered for a local or systemic (either enteral [through the digestive tract] or parenteral [outside the digestive tract]) effect. Intravenous (IV): Administration of substance into venous circulation. The development of dosage forms draws on the discipline of biopharmaceutics, which integrates an understanding of formulations, dissolution, stability, and controlled release (pharmaceutics); absorption, distribution, metabolism, and excretion (ADME; pharmacokinetics, or PK protocol).
